

ABSTRACT:

This data transmission system is formed by at least a mobile radio station (1) including a site explorer (2) and by at least a WAP data server (20) that concludes a list of names of accessible files (24). To these names of accessible files is associated an URL address which defines:

- a preparation of the activation of said station for an application (dev),
- an application (appli. xxx),
- an IP address for defining the address of the server of the accessible file (Iphx),
- the name of the accessible file (filnamex),
- the possible parameters for this file (parameter).

The invention does not have the constraints of filter devices of the Internet world, so that files for a mobile WAP can be accessed via the Internet.

Application: WAP navigation.
